Abstract

In urban areas, the nitrate contamination is rampant and much attention has not been drawn towards this anthropogenic pollution. To assess the hydrochemical composition and status of nitrate (NO₃⁻) in groundwater, a total of 240 groundwater samples from shallow and deep aquifers were collected during pre- and post-monsoon seasons from Nagpur city. The study revealed that groundwater was found unsuitable for drinking purposes due to high NO₃⁻ concentration. Seasonal variation in NO₃⁻ concentration was observed in both aquifers. The results of this study are useful to highlight one of the most important environmental problems, namely the degradation of the water quality.

Keywords: Groundwater quality; nitrate pollution; anthropogenic input; Nagpur city.
